Pages	Pages 8181–8189
Abstracts	<p>Seedlings of durum wheat [<i>Triticum turgidum</i> subsp. durum (Desf.) Husn] were exposed to zinc nutrition and to ozone (O₃) in a factorial combination: adequate (+Zn treatment) or no Zn (–Zn) in the nutrient solution, followed by exposure to either ozone-free air (filtered air, FA) or to 150 nL L⁻¹ ozone (O₃) for 4 h. Although omitting Zn from the nutrient solution failed to impose a genuine Zn deficiency, –Zn*FA durum wheat seedlings showed a typical deficiency behaviour, i.e. Zn mobilisation from root to shoot. Such inter-organ Zn redistribution, however, did not occur in –Zn*O₃ plants. Exposures to each stress singly decreased the activity and the protein amount of foliar plasma membrane H⁺-ATPase, but not stress combination, which even increased the H⁺-ATPase expression with respect to control. In the –Zn*O₃ plants, moreover, the foliar activities of the plasma membrane-bound NAD(P)H-dependent superoxide synthase and of Cu, Zn-superoxide dismutase, and the transcripts abundance of the luminal binding protein and of the protein disulphide isomerase, were also stimulated. It is proposed that, even in the absence of actual Zn starvation, the perception of deficiency conditions could trigger changes in redox homeostasis at the plasma membrane level, helpful in compensating an O₃- dependent oxidative damage.</p>

Title	Exposure- and flux-based assessment of ozone risk to sugarcane plants
Author Name	Barbara Baesso Moura, Yasutomo Hoshika, Rafael Vasconcelos Ribeiro, Elena Paolettib
Journal Name	Atmospheric Environment
Year	2018
Volume and Issue	176
Pages	252-260
Abstracts	<p>Ozone (O₃) is a toxic oxidative air pollutant, with significant detrimental effects on crops. Sugarcane (<i>Saccharum</i> spp.) is an important crop with no O₃ risk assessment performed so far. This study aimed to assess O₃ risk to sugarcane plants by using exposure-based indices (AOT40 and W126) based on O₃ concentrations in the air, and the flux-based index (POD_y, where <i>y</i> is a threshold of uptake) that considers leaf O₃ uptake and the influence of environmental conditions on stomatal conductance (<i>g</i>_{st}). Two sugarcane genotypes (IACSP94-2094 and IACSP95-5000) were subjected to a 90-day Free-Air Controlled Experiment (FACE) exposure at three levels of O₃ concentrations: ambient (Amb); Amb x1.2; and Amb x1.4. Total above-ground biomass (AGB), stalk biomass (SB) and leaf biomass (LB) were evaluated and the potential biomass production in a clean air was estimated by assuming a theoretical clean atmosphere at 10 ppb as 24 h O₃ average. The Jarvis-type multiplicative algorithm was used to parametrize <i>g</i>_{st} including environmental factors i.e. air temperature, light intensity, air vapor pressure deficit, and minimum night-time temperature. Ozone exposure caused a negative impact on AGB, SB and LB. The O₃ sensitivity of sugarcane may be related to its high <i>g</i>_{st} (~535 mmol H₂O m⁻² s⁻¹). As sugarcane is adapted to hot climate conditions, <i>g</i>_{st} was restricted when the current minimum air temperature (<i>T</i>_{min}) was below ~14 °C and the minimum night-time air temperature of the previous day (<i>T</i>_{nmin}) was below ~7.5 °C. The flux-based index (POD_y) performed better than the exposure-based indices in estimating O₃ effect on biomass losses. We recommend a <i>y</i> threshold of 2 nmol m⁻² s⁻¹ to incorporate O₃ effects on both AGB and SB and 1 nmol m⁻² s⁻¹ on LB. In order not to exceed 4% reduction in the growth of these two sugarcane genotypes, we recommend the following critical levels: 1.09 and 1.04 mmol m⁻² POD₂ for AGB, 0.91 and 0.96 mmol m⁻² POD₂ for SB, and 3.00 and 2.36 mmol m⁻² POD₁ for LB of IACSP95-5000 and IACSP94-2094, respectively.</p>

Title	Tropospheric ozone pollution in India: effects on crop yield and product quality
Author Name	Aditya Abha Singh & S. B. Agrawal
Journal Name	Environmental Science and Pollution Research
Volume and Issue	24,5
Year	2017
Pages	4367–4382
Abstracts	<p>Ozone (O₃) in troposphere is the most critical secondary air pollutant, and being phytotoxic causes substantial losses to agricultural productivity. Its increasing concentration in India particularly in Indo-Gangetic plains is an issue of major concern as it is posing a threat to agriculture. In view of the issue of rising surface level of O₃ in India, the aim of this compilation is to present the past and the prevailing concentrations of O₃ and its important precursor (oxides of nitrogen) over the Indian region. The resulting magnitude of reductions in crop productivity as well as alteration in the quality of the product attributable to tropospheric O₃ has also been taken up. Studies in relation to yield measurements have been conducted predominantly in open top chambers (OTCs) and also assessed by using antiozonant ethylene diurea (EDU). There is a substantial spatial difference in O₃ distribution at different places displaying variable O₃ concentrations due to seasonal and geographical variations. This review further recognizes the major information lacuna and also highlights future perspectives to get the grips with rising trend of ground level O₃ pollution and also to formulate the policies to check the emissions of O₃ precursors in India.</p>

Title	Effects of Ozone on Japanese Trees
Author Name	Makoto Watanabe , Yasutomo Hoshika, Takayoshi Koike, Takeshi Izuta
Journal Name	Air Pollution Impacts on Plants in East Asia
Year	2016
Pages	73-100
Abstracts	<p>The effects of ozone (O₃) on tree species in Japan have been studied since the 1970s. Based on the results from O₃ fumigation studies, current ambient levels of O₃ have negative impacts on the growth and physiological functions of Japanese forest tree species, although there is a big variation of O₃ sensitivity between species. Stomatal O₃ uptake is one of the key factors that can explain the differences in O₃ sensitivity between species and modeling of this factor has been intensively studied during the past decade. Although O₃ generally induces stomatal closure, less efficient stomatal control, so-called stomatal sluggishness, is also induced by chronic exposure to O₃. These opposite phenomena result in complex responses of stomata to O₃. Detailed gas exchange analysis has revealed that O₃-induced reductions in the photosynthetic rate of Japanese forest tree species were mainly due to a biochemical limitation in chloroplasts, but not due to stomatal closure. Risk assessments of the O₃ impact on Japanese forest tree species, based on the results of experimental studies, national monitoring data of air pollutant concentrations, and vegetation surveys, indicate that the areas with high O₃-induced reduction in growth do not necessarily correspond to the areas with relatively high O₃ exposure. Free-air O₃ fumigation systems in Japan were developed in 2011. Studies with this novel technology have clarified differences in leaf O₃ sensitivities between canopy positions, and have estimated the effects of O₃ on whole-canopy carbon budgets. As future perspectives, not only we need clarification of the physiological mechanisms of O₃ impact, but we also need clarification of the effects of interactions between trees and other biotic factors such as diseases, herbivores, and symbiotic microbes.</p>

Title	How do increasing background concentrations of tropospheric ozone affect peatland plant growth and carbon gas exchange?
Author Name	Jennifer L. Williamson, Gina Mills, Felicity Hayes, Timothy Jones ,Chris Freeman
Journal Name	Atmospheric Environment
Year	2016
Volume and Issue	Volume 127
Pages	133–138
Abstracts	In this study we have demonstrated that plants originating from upland peat bogs are sensitive to increasing background concentrations of ozone. Peatland mesocosms from an upland peat bog in North Wales, UK were exposed to eight levels of elevated background ozone in solardomes for 4 months from May to August, with 24 h mean ozone concentrations ranging from 16 to 94 ppb and cumulative AOT024hr ranging from 45.98 ppm h to 259.63 ppm h. Our results show that plant senescence increased with increasing exposure to ozone, although there was no significant effect of increasing ozone on plant biomass. Assessments of carbon dioxide and methane fluxes from the mesocosms suggests that there was no change in carbon dioxide fluxes over the 4 month exposure period but that methane fluxes increased as cumulative ozone exposure increased to a maximum AOT 024hr of approximately 120 ppm h and then decreased as cumulative ozone exposure increased further.

Title	Effects of Ozone on Chinese Trees
Author Name	Zhaozhong Feng , Pin Li
Journal Name	Air Pollution Impacts on Plants in East Asia
Year	2016
Pages	195-219
Abstracts	<p>This chapter reviews the effects of elevated ozone on tree species in China, based on the results of studies in the past two decades. The high ozone concentration in summer in most parts of China has induced typical ozone symptoms in urban and mountain forest tree species. In experiments using open-top chambers, elevated ozone affected the growth, gas-exchange rate, foliar microscopy, antioxidant systems, and biogenic volatile organic compound (BVOC) emissions in trees. The effects of ozone on biomass accumulation depended on the ozone concentration, tree species sensitivity, and exposure duration. The ozone uptake of individual tree species was also investigated by the sap flow technique. Further studies were conducted on the interactions between O₃ and other environmental change factors, such as increasing CO₂ concentrations, increased nitrogen deposition, and drought. Future needs for research include the development of an O₃ flux model for the most widely used tree species and the assessment of ozone removal by urban forests on a regional and a national scale.</p>

Title	Leaf traits and photosynthetic responses of <i>Betula pendula</i> saplings to a range of ground-level ozone concentrations at a range of nitrogen loads
Author Name	Harry Harmens, Felicity Hayes, Katrina Sharps, Gina Mills, Vicent Calatayud
Journal Name	Journal of Plant Physiology
Year	2016
Volume and Issue	Volume 211
Pages	42–52
Abstracts	<p>Ground-level ozone (O₃) concentrations and atmospheric nitrogen (N) deposition rates have increased strongly since the 1950s. Rising ground-level O₃ concentrations and atmospheric N deposition both affect plant physiology and growth, however, impacts have often been studied in isolation rather than in combination. In addition, studies are often limited to a control treatment and one or two elevated levels of ozone and/or nitrogen supply. In the current study, three-year old <i>Betula pendula</i> saplings were exposed to seven different O₃ profiles (24 h mean O₃ concentration of 36–68 ppb in 2013, with peaks up to an average of 105 ppb) in precision-controlled hemispherical glasshouses (solar domes) and four different N loads (10, 30, 50 or 70 kg N ha⁻¹ y⁻¹) in 2012 and 2013. Here we report on the effects of enhanced O₃ concentrations and N load on leaf traits and gas exchange in leaves of varying age and developmental stage in 2013. The response of leaf traits to O₃ (but not N) vary with leaf developmental stage. For example, elevated O₃ did not affect the chlorophyll content of the youngest fully expanded leaf, but it reduced the chlorophyll content and photosynthetic parameters in aging leaves, relatively more so later than earlier in the growing season. Elevated O₃ enhanced the N content of senesced leaves prior to leaf fall, potentially affecting subsequent N cycling in the soil. Enhanced N generally stimulated the chlorophyll content and photosynthetic capacity. Whilst elevated O₃ reduced the light-saturated rate of photosynthesis (A_{sat}) in aging leaves, it did not affect stomatal conductance (g_s). This suggests that photosynthesis and g_s are not closely coupled at elevated O₃ under light saturating conditions. We did not observe any interactions between O₃ and N regarding photosynthetic parameters (V_{c,max}, J_{max}, A_{sat}), chlorophyll content, g_s, N content in senesced leaves and leaf number. Hence, the sensitivity of these leaf traits to O₃ in young silver birch trees is neither reduced nor enhanced by N load.</p>

Year	2016
Volume and Issue	Volume 45,1
Pages	224-233
Abstracts	<p>A crucial issue in urban environments is the interaction between urban trees and atmospheric pollution, particularly ozone (O₃). Ozone represents one of the most harmful pollutants in urban and peri-urban environments, especially in warm climates. Besides the large interest in reducing anthropogenic and biogenic precursors of O₃ emissions, there is growing scientific activity aimed at understanding O₃ removal by vegetation, particularly trees. The intent of this paper is to provide the state of the art and suggestions to improve future studies of O₃ fluxes and to discuss implications of O₃ flux studies to maximize environmental services through the planning and management of urban forests. To evaluate and quantify the potential of O₃ removal in urban and peri-urban forests, we describe experimental approaches to measure O₃ fluxes, distinguishing laboratory experiments, field measurements, and model estimates, including recent case studies. We discuss the strengths and weaknesses of the different approaches and conclude that the combination of the three levels of investigation is essential for estimating O₃ removal by urban trees. We also comment on the implications of these findings for planning and management of urban forests, suggesting some key issues that should be considered to maximize O₃ removal by urban and peri-urban forests.</p>

Title	Responses of a tropical tree species to ozone: visible leaf injury, growth, and lipid peroxidation.
Author Name	Essica C. Cassimiro, Regina M. Moraes
Journal Name	Environmental Science and Pollution Research
Year	2016
Volume and Issue	Volume 23, 8
Pages	8085–8090
Abstracts	<p>The Brazilian native tree species <i>Astronium graveolens</i> was indicated as sensitive to ozone in a fumigation experiment. Thus, the objective of this study was to evaluate how sensitive <i>A. graveolens</i> is to ozone under realistic conditions in the field. Eighteen saplings were exposed to ozone in a contaminated area and in a greenhouse with filtered air during two exposure periods of approximately 63 days each (March–May 2012 and September–October 2012). Leaf injury was analyzed by means of its incidence and severity, the leaf injury index (LII) and the progression of leaf abscission. These variables were monitored weekly, whereas growth and lipid peroxidation were monitored monthly. Plants exposed to ozone showed significant growth decrease and visible leaf injury increase, but lipid peroxidation and leaf abscission remained unchanged. These results indicated that plants subjected to ozone possibly diverted energy from growth to the production of antioxidants necessary to cope with ozone-induced oxidative stress.</p>

Journal Name	Chemosphere
Year	2016
Volume and Issue	Volume 172
Pages	363–372
Abstracts	<p>Tropospheric ozone (O₃) is a major air pollutant and greenhouse gas, affecting carbon dynamics, ecological interactions, and agricultural productivity across continents and biomes. Elevated [O₃] has been documented in tropical evergreen forests, the epicenters of terrestrial primary productivity and plant-consumer interactions. However, the effects of O₃ on vegetation have not previously been studied in these forests. In this study, we quantified ambient O₃ in a region shared by forests and urban/commercial zones in Panama and found levels two to three times greater than in remote tropical sites. We examined the effects of these ambient O₃ levels on the growth and chemistry of seedlings of <i>Ficus insipida</i>, a regionally widespread tree with high stomatal conductance, using open-top chambers supplied with ozone-free or ambient air. We evaluated the differences across treatments in biomass and, using UPLC-MS-MS, leaf secondary metabolites and membrane lipids. Mean [O₃] in ambient air was below the levels that induce chronic stress in temperate broadleaved trees, and biomass did not differ across treatments. However, leaf secondary metabolites – including phenolics and a terpenoid – were significantly downregulated in the ambient air treatment. Membrane lipids were present at lower concentrations in older leaves grown in ambient air, suggesting accelerated senescence. Thus, in a tree species with high O₃ uptake via high stomatal conductance, current ambient [O₃] in Panamanian forests are sufficient to induce chronic effects on leaf chemistry.</p>
